Numerical Optimisation. Project 1

Team Information

Group 1
Participants information in alphabetical order

#	Name	Lastname	Matr Number
1	David	Kürnsteiner	11820336
2	Christian	Peinthor	11815592
3	Elias	Ramoser	11918558
4	Georg	Storz	11918811

Implementation

All points x are represented as numpy arrays. Function f returns a scalar with grad_f and hessian_f returning numpy arrays.

Imports

Describe how to install additional packages, if you have some, here

In [1]:
```
import numpy as np
import scipy
import pandas as pd
from matplotlib import pyplot as plt
import seaborn as sns
from numpy.linalg import *
from sklearn.datasets import make_spd_matrix
```

Stopping criteria

Function returns True if the gradient of f at xk relative to x0 is smaller than parameter tol.

Additionally there is an upper bound for iterations to stop non converging algorithms.

In [2]:
```
def stop_crit(grad_f, xk, x0, i, tol=1e-8, max_iter=5000):
  if i > max_iter:
    return True
  elif norm(grad_f(xk)) <= tol * norm(grad_f(x0)):
    return True
  return False
```

Varibales scaling

Place your reasoning here, how your algorithm behave with respect to this problem. You can also try rescaling your problems This is additional task, which can earn you several points.

In [ ]:
```

```

Stabilising algorithm

Place your reasoning here, how your algorithm behave with respect to this problem. You can also try rescaling your problems This is additional task, which can earn you several points.

In [3]:
```
#your function for stabilising goes here
```

Fighting floating-point numbers and roundoff error

Place your reasoning, how your algorithm behave with respect to this problem. You can also try rescaling your problems This is additional task, which can earn you several points.

Inverting matrices

linear_solve() provides a way to solve linear systems of equations using a LU-factorization of A and subsequent forward and backward substitution as described in the book. This solver proves to be quite unstable though in practical applications. We therefore use the numpy implementation of solve().

In [4]:
```
def forward_substitution(L, b):

    n = L.shape[0]
```

```python
    y = np.zeros_like(b, dtype=np.double);

    y[0] = b[0] / L[0, 0]

    for i in range(1, n):
        y[i] = (b[i] - np.dot(L[i,:i], y[:i])) / L[i,i]

    return y

def back_substitution(U, y):

    n = U.shape[0]

    x = np.zeros_like(y, dtype=np.double);

    x[-1] = y[-1] / U[-1, -1]

    for i in range(n-2, -1, -1):
        x[i] = (y[i] - np.dot(U[i,i:], x[i:])) / U[i,i]

    return x

def linear_solve(A, b):

    P, L, U = scipy.linalg.lu(A)

    y = forward_substitution(L, P @ b)

    return back_substitution(U, y)
```

Gradients calculation

Following functions are wrapper functions that provide approximations of the gradient and hessian of f using the forward-difference approach as described in the book.

In [5]:

```python
def e_i(size, index):
  arr = np.zeros(size)
  arr[index] = 1.0
  return arr

def approx_grad(f, e=1.1*10**-8):
  def grad_f(x):
    if x.size == 1:
      return (f(x + e) - f(x)) / e
    return np.array([(f(x + e * e_i(x.size, i)) - f(x)) / e for i in range(x.size)])
  return grad_f

def approx_hessian(f, e=1.1*10**-8):
  def hessian_f(x):
    if x.size == 1:
      return (f(x + 2*e) - 2*f(x + e) + f(x)) / e**2
    return np.array([[(f(x + e * e_i(x.size, i) + e * e_i(x.size, j)) - f(
                      x + e * e_i(x.size, i)) - f(x + e * e_i(x.size, j)) + f(
                      x)) / e**2 for j in range(x.size)] for i in range(x.size)])
  return hessian_f
```

Additional objects you implemented

The class Problem() provides an object to generate and set up quadratic and non some non quadratic test problems for the algorithms with.

In [6]:

```
class Problem():

  def __init__(self):

    self.f = None
    self.grad_f = None
    self.hessian_f = None
    self.min_x = None

  def quadratic(self, n_dim, rseed):

    rng = np.random.RandomState(rseed)
    A = make_spd_matrix(n_dim, random_state=rseed)
    x = rng.randint(-10, 10, n_dim)
    b = A @ x

    def f(x):
      return 0.5 * x.T @ A @ x - b @ x

    def grad_f(x):
      return A @ x - b

    def hessian_f(x):
      return A

    self.f = f
    self.grad_f = grad_f
    self.hessian_f = hessian_f
    self.min_x = x
    self.A = A
    self.b = b

  def rosenbrock(self):

    def f(x):
      return 100*(x[1] - x[0]**2)**2 + (1 - x[0])**2

    def grad_f(x):
      return np.array([-400*x[0]*(x[1] - x[0]**2) - 2*(1 - x[0]),
          200*(x[1] - x[0]**2)])

    def hessian_f(x):
      return np.array([[-400*(x[1] - 3*x[0]**2) + 2, -400*x[0]],
          [-400*x[0], 200]])

    self.f = f
    self.grad_f = grad_f
    self.hessian_f = hessian_f
    self.min_x = np.array([1,1])

  def himmelblau(self):

    def f(x):
      return (x[0] ** 2 + x[1] - 11) ** 2 + (x[0] + x[1] ** 2 - 7) ** 2

    def grad_f(x):
```

```python
      return np.array([4*x[0]*(x[0]**2 + x[1] - 11)+2*(x[0] + x[1]**2 - 7),
                        4*x[1]*(x[1]**2 + x[0] - 7)+2*(x[1] + x[0]**2 - 11)])

    def hessian_f(x):
      return np.array([[12*x[0]**2 + 4*x[1] - 42, 4*(x[1] + x[0])],
                        [4*(x[1] + x[0]), 12*x[1]**2 + 4*x[0] - 26]])

    self.f = f
    self.grad_f = grad_f
    self.hessian_f = hessian_f
    self.min_x = np.array([[3,2], [-2.805118, 3.131312], [-3.779310, -3.283186], [3.

  def poly_1(self):

    def f(x):
      return ((x - 7)**2 * (x - 3)**2) / 4

    def grad_f(x):
      return (x - 7) * (x - 5) * (x - 3)

    def hessian_f(x):
      return 3 * x**2 - 30 * x + 71

    self.f = f
    self.grad_f = grad_f
    self.hessian_f = hessian_f
    self.min_x = np.array([[3],[5],[7]])

  def poly_2(self):

    def f(x):
      return (x**2 * (x**2 - 16*x + 40)) / 4

    def grad_f(x):
      return x * (x - 2) * (x - 10)

    def hessian_f(x):
      return 3 * x**2 - 24 * x + 20

    self.f = f
    self.grad_f = grad_f
    self.hessian_f = hessian_f
    self.min_x = np.array([[0],[2],[10]])

  def poly_3(self):

    def f(x):
      return (x * (3 * x**3 - 64 * x**2 + 414 * x - 648)) / 12

    def grad_f(x):
      return (x - 1) * (x - 6) * (x - 9)

    def hessian_f(x):
      return 3 * x**2 - 32 * x + 69

    self.f = f
    self.grad_f = grad_f
    self.hessian_f = hessian_f
    self.min_x = np.array([[1],[6],[9]])
```

Optimising algorithm itself

backtracking_alpha() implements the backtracking line search to find a suitable step length as described in the book. FR() implements the Fletcher Reeves nonlinear conjugate gradient method.

In [7]:

```
def backtracking_alpha(f, grad_f, xk, pk, alpha0=1, rho=0.95, c=1e-4):

  alpha = alpha0

  while not f(xk + alpha * pk) <= (f(xk) + c * alpha * grad_f(xk).T @ pk):
    alpha *= rho

  return alpha

def FR(x0, f, grad_f=None):

  conv_tol = 1e-8
  if grad_f == None:
    grad_f = approx_grad(f)
    conv_tol = 1e-6
  i = 0
  xk = x0
  pk = -grad_f(xk)

  while not stop_crit(grad_f, xk, x0, i, tol=conv_tol):

    xk1 = xk + backtracking_alpha(f, grad_f, xk, pk) * pk
    beta = (grad_f(xk1) @ grad_f(xk1)) / (grad_f(xk) @ grad_f(xk))
    pk = -grad_f(xk1) + beta * pk
    xk = xk1
    i += 1

  print(f"\nsearch terminated at iteration {i} | result: {xk}")
  return xk
```

Testing on 5-10 variables, Quadratic objective

Implement functions to optimise over

Place for additional comments and argumentation

In [8]:

```
rseed = [1,4,6,7,8]
quadratic_probs = []
for i in range(5):
  prob = Problem()
  prob.quadratic(10, rseed[i])
  quadratic_probs.append(prob)
```

Run 5 tests

Note: *After every test print out the resulsts.*
For your convinience we implemented a function which will do it for you. Function can be used in case after running optimisation you return $x_{optimal}$, and if you have implemented your gradient approximation. Feel free to bring your adjustments.
Additionaly print how many iterations your algotithm needed. You might also provide charts of your taste (if you want).

Place for your additional comments and argumentation

In [9]:
```
def final_printout(x_0,x_optimal,x_appr,f,grad,args,tolerance):

For non quadratic functions the conjugent gradient outperforms the steepest descent algorithm nearly all the time, while the other two algorithms are faster, if they even get a result.

Template for teachers' tests

Set up a template, how one can run your code

Template should include sceletons for:

- *custom function to optimise over*
- *values initialisation to submit into otimising algorithm*
- *optimiser function call*
- *report print out call*

Provide descriptions and comments.

In [12]:

```
algorithm_to_test = FR

# Here you can set your individual starting point
x_0 = np.ones(10)

# Here you can enter your individual function
def f(x):
    return np.sum(np.square(x))

# Here you can enter the exact gradient of your function
# This function will just be used in the second test
def grad_f(x):
    return 2*x

# Test run:

print("Test with approximate gradient:")
algorithm_to_test(x_0, f)
```

```python
print('\n'*2) # Print some lines between the tests

print("Test with exact gradient:")
algorithm_to_test(x_0, f, grad_f)

print()
```
